Height: the asymmetry is a rare single hit acting on the duplication axis

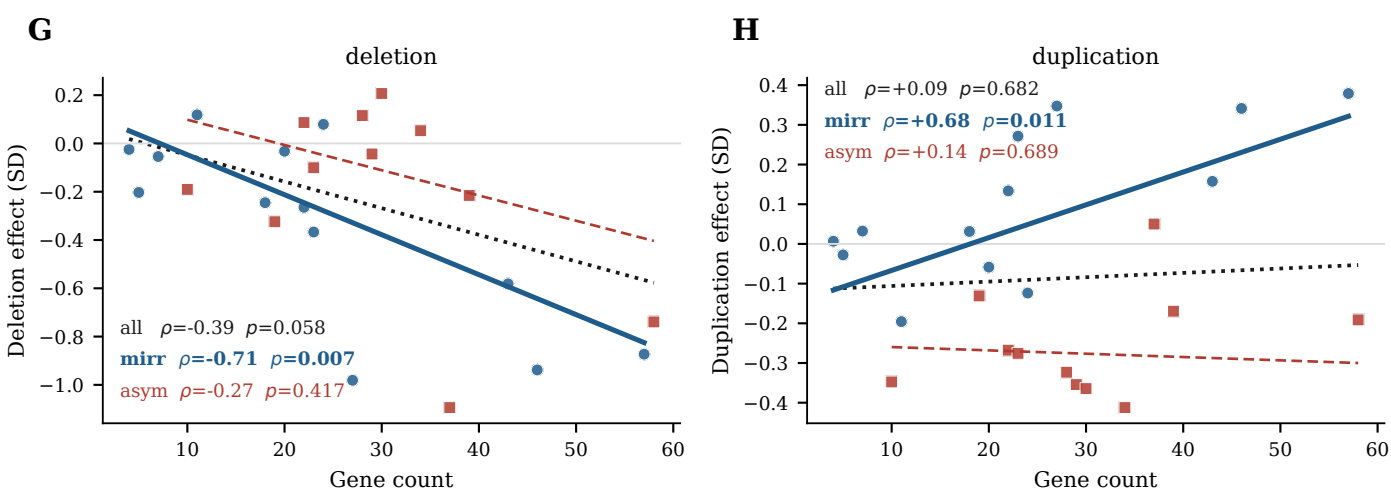

1. Is the perpendicular offset from the mirror line bimodal?

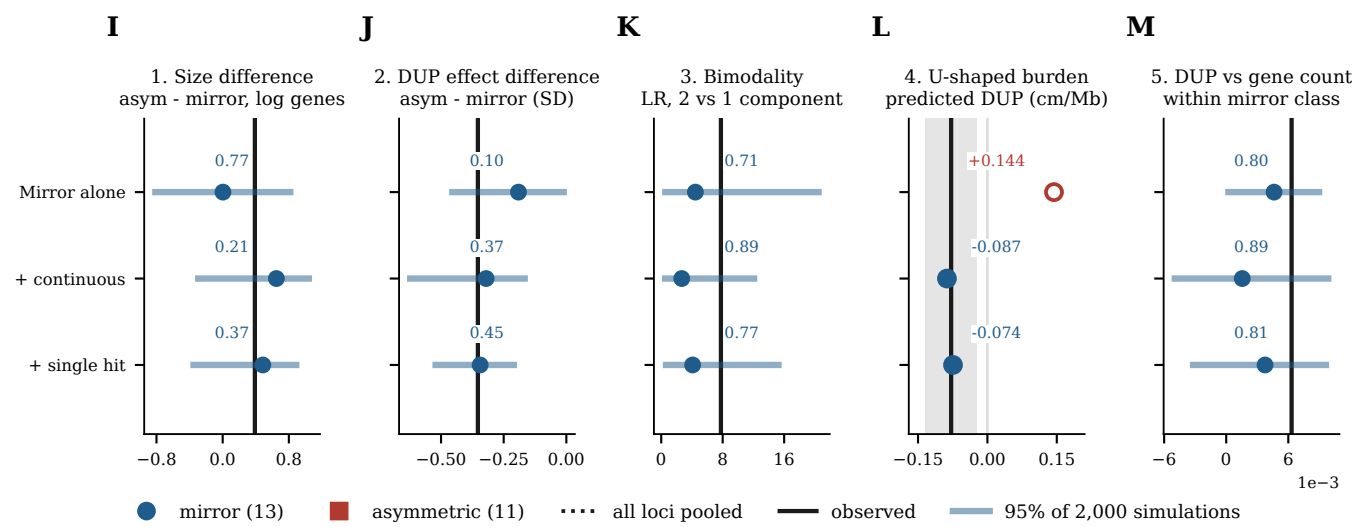

2. Mirror and asymmetric CNVs differ by size and DUP effect, not DEL

3. Effect size scales with gene count only after stratifying by class

4. Both directional models satisfy all five criteria; mirror alone fails the burden

I-K, M: the number above each bar is the percentile of the observed value in that model's 2,000 simulations; blue = inside the central 90%.
L: grey band is the published 95% CI (Macé et al. 2017); the deletion burden is the calibration anchor, so the duplication burden is an out-of-sample prediction.
A-H: Excludes loci where neither DEL nor DUP reaches p < 0.05; the mirror line is refitted on the rest.
I-M: models fitted on all 33 loci; the same p < 0.05 exclusion is applied to the observed data and to every simulated replicate before scoring.
