Height: the asymmetry is a rare single hit acting on the duplication axis

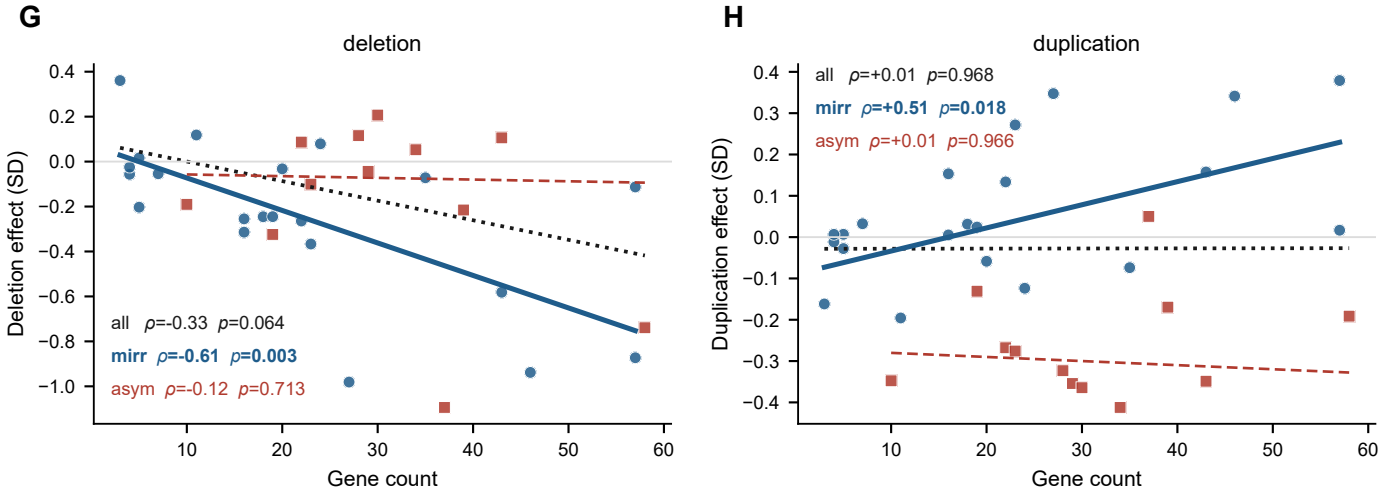

1. The perpendicular offset from the mirror line is bimodal

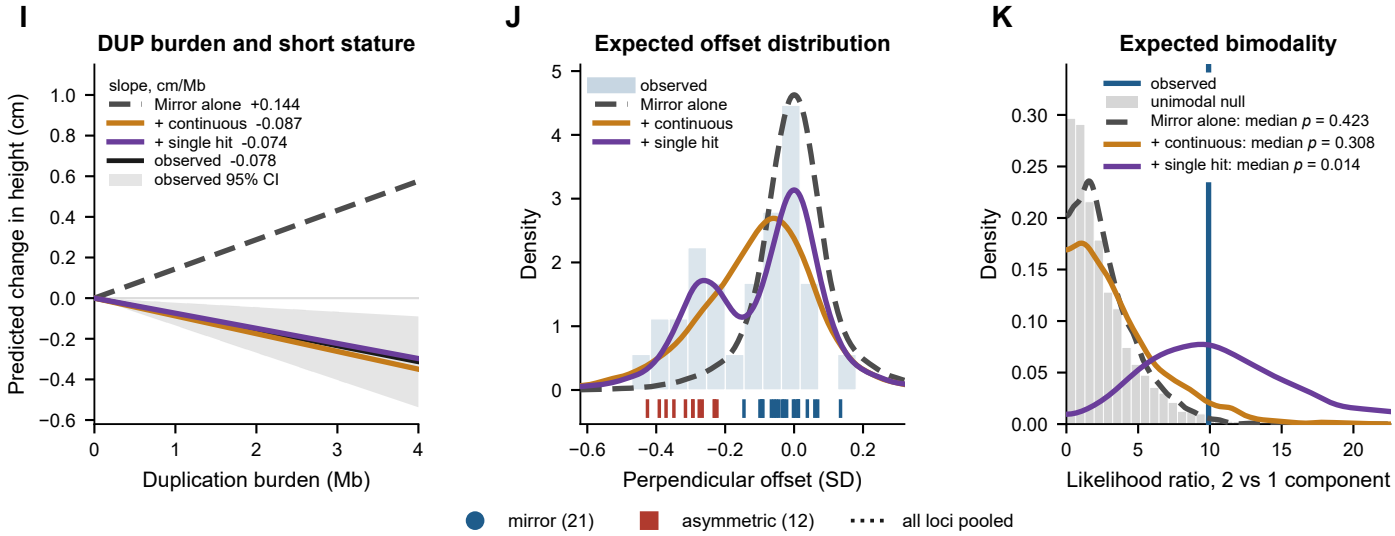

2. Mirror and asymmetric CNVs differ by size and DUP effect, not DEL

3. Effect size scales with gene count only after stratifying by class

4. Where the models differ: duplication burden and bimodality

I: each model is calibrated so its deletion burden equals the published -0.41 cm/Mb (Macé et al. 2017); its duplication slope is then an out-of-sample prediction. Grey band = published 95% CI.
J, K: each model's 2,000 simulated datasets (real gene counts and SEs). J pools their offsets; K shows their likelihood ratios. Median p = the typical dataset's p against the unimodal null in B.
Bimodality (A, B, J, K) uses the measurement-error-aware mixture: each locus's offset SE enters both fits.
